Overview

Is this not the cutest little display for the Raspberry Pi? It features a 2.8" display with 320x240 16-bit color pixels and a resistive touch overlay. The plate uses the high speed SPI interface on the Pi and can use the mini display as a console, X window port, displaying images or video etc. Best of all it plugs right in on top!

It's designed to fit nicely onto the Pi Model A or B but also works perfectly fine with the Pi 2 or Model B+ as long as you don't mind the PCB overhangs the USB ports by 5mm
This design uses the hardware SPI pins (SCK, MOSI, MISO, CE0, CE1) as well as GPIO #25 and #24. All other GPIO are unused. Since we had a tiny bit of space, there’s 4 spots for optional slim tactile switches wired to four GPIOs, that you can use if you want to make a basic user interface. For example, you can use one as a power on/off button.

We bring out GPIO #23, #22, #21, and #18 to the four switch locations!
To make it super easy for use: we’ve created a custom kernel package based off Notro’s awesome framebuffer work, so you can install it over your existing Raspbian (or derivative) images in just a few commands.
This tutorial series shows you how to install the software, as well as calibrate the touchscreen, splay videos, display images such as from your PiCam and more!
Assembly

This tutorial page is for PiTFT that came as a kit. If your PiTFT is already assembled, skip this step!

Before you start check that you have the parts you need: an assembled PiTFT plate with the 2.8” screen, extra tall female header and the 2x13 IDC socket. Note that it is normal for the screen to be ‘loose’ - this is so its easier for you to solder the connector on!
Check also on the back that the TFT is attached and that the flex connector is seated into the onboard FPC socket.

The easiest way to attach the header is if you have a Raspberry Pi as a 'stand' - make sure its powered off & unplugged!
Plug the extra tall female header into the GPIO port on the Pi as shown. Make sure its seated nice and flat.

Place the PiTFT shield on top so all the pins stick through the connector on the side. Gently flip the TFT so its off to the side and wont be in your way while you solder.

Heat up your soldering iron, and grab some solder. Start by tack-soldering one of the corners while pressing on the plate to make it sit flat. Once you have one or two pins done you can continue to solder each of the pins.
Before attaching the display, check that all the pins are soldered nicely and there's no bridging, cold.
solder, shorts, or unsoldered pins.

Now we can attach the screen. Remove the two thin tape cover strips.

Line up the screen on the white outline, make sure there's some space from the header you just soldered in and the metal sides of the screen. As long as you don't really press down on the screen you can reposition it once or twice.
Once you have the screen so it is definitely not touching the header, you can gently press on the sides to secure the tape.

If the protective plastic cover is still on the screen you can press it against a clean table from above. That way you will really securely attach it!

If you want to attach an Adafruit Cobbler or similar, you can solder in the optional 2x13 IDC on the **bottom** of the screen as shown here. This will keep the top side clean and flat. Solder in all 26 pins.

The picture shows a 2x13 male header. We've since updated this product to include an IDC socket so it's easier to add a cobbler. Both will work, though!
You can attach a 26-pin IDC cable just make sure the pin 1 indicator is on the right as indicated in this photo - there's also a #1 marking on the PCB!
Easy Install

The PiTFT requires kernel support and a couple other things to make it a nice stand-alone display. We have a detailed step-by-step setup for hackers who want to tweak, customize or understand the PiTFT setup. If you just want to get going, check out the following for easy-install instructions!

Ready to go image

If you want to start with a fresh image, we have one for Raspbian - click here to download it and install into a new SD card. Unzip and follow the classic SD card burning tutorials (http://adafru.it/aMW)

Download PiTFT 2.4" and 2.8"
Resistive Image for Pi 1 and Pi 2
(September 9, 2015)
http://adafru.it/idJ

This image is customized for the RESISTIVE touch 2.8" TFT, also known as PID #1601, or the Resistive 2.4" HAT, a.k.a PID #2455 Not for PID #1983

Previous images:

- Raspbian 2014/06/20-based image (http://adafru.it/dSM)
- Raspbian 2014/09/09-based image (http://adafru.it/e12)

DIY Installer script

If you don’t want to download an image, you can run our installation package helper from inside your existing Raspbian install. It will download the kernel add-ons, and configure your Pi for PiTFT joy

The helper is available for perusal here (http://adafru.it/eIn) if you are interested in how it works

To download and run it, simply run the following commands:

curl -SLs https://apt.adafruit.com/add-pin | sudo bash
sudo apt-get install raspberrypi-bootloader
sudo apt-get install adafruit-pitft-helper

The first command adds apt.adafruit.com to your repository list, so you can grab code directly from
The next two do the actual download and installation, it'll take a while because there's a lot of software to replace for PiTFT support.

Note: The `apt-get install raspberrypi-bootloader` command installs a specific version of the bootloader that uses an Adafruit-compiled kernel version. Don't use the `rpi-update` command to update the firmware/kernel to the Pi Foundation's 4.x version as it is not supported by the PiTFT right now.
It's normal for the Pi to pause and/or take a while at this step for many minutes, there's a lot of kernel software to replace.
OK now the kernel and helper are installed, all you have to do is run the helper which will configure the kernel device tree overlays and add the few configurations to make the console show up, etc.

```bash
sudo adafruit-pitft-helper -t 28r
```

This will install the "2.8 Resistive" type of PiTFT into the current install. This is the same as the 2.4" Resistive screen too (same resolution, pinout, etc.)

At the end you will be prompted on whether you want the text console to appear on the PiTFT. Answer Y or N depending on your personal desires!
You will also be prompted on whether you want one of the tactile buttons to act as an 'on off' switch. Answer Y or N depending on your personal desires!

Thats it!

Run sudo reboot to try out your fancy new PiTFT :)

Remember the PiTFT currently only works with Adafruit's Linux kernel. Don't use the rpi-
update command or else it will download a Pi Foundation 4.x kernel and break the PiTFT support!
In the next few steps we'll cover the detailed installation procedure. Chances are, you should grab the Easy Install image or script. If you have some interest in the details of how we install the PiTFT setup, read on!

In order to add support for the 2.4" or 2.8" TFT and touchscreen, we'll need to install a new Linux Kernel. Lucky for you, we created a kernel package that you can simply install over your current Raspbian (or Raspbian-derived) install instead of needing a whole new image. This makes it easier to keep your install up-to-date.

To use our kernel .deb files you must be using Raspbian or a derivative. This won't work with Arch or other Linux flavors. As Raspbian is the official OS for the Pi, that's the only Linux we will support!
Others can recompile their own kernel using our patchfile (http://adafruit.it/cY2), but we have no tutorial or support or plans for such.

**Before you start**

You'll need a working install of Raspbian with network access. If you need help getting that far, check out our collection of Pi tutorials (http://adafruit.it/aWq).

We'll be doing this from a console cable connection, but you can just as easily do it from the direct HDMI/TV console or by SSH'ing in. Whatever gets you to a shell will work!

Also, run **sudo apt-get update**!

To run these all the setup and config commands you'll need to be logged into a proper Terminal - use ssh, a console cable, or the main text console (on a TV). The WebIDE console may not work.

**Download & Install Kernel**

The only way we're distributing the PiTFT kernel packages right now is thru apt.adafruit.com so you'll still need to run:

```bash
curl -SLs https://apt.adafruit.com/add-pin | sudo bash
```

To add apt.adafruit.com to your list of software sources
Then install the kernel with

```bash
sudo apt-get install raspberrypi-bootloader
```

This will take a up to 20 minutes so go make a sandwich or coffee. It takes longer than it used to because there's now 2 kernels (v6 and v7 arm) and 2 kernel module directories.

**Note:** The `apt-get install raspberrypi-bootloader` command installs a specific version of the bootloader compiled by Adafruit. Don't use the `rpi-update` command to update the firmware/kernel to the Pi Foundation’s 4.x version as it is not supported by the PiTFT right now.

Don't use `rpi-update`!
OK since you're not going to run the helper, let's add the device tree overlay manually. Edit /boot/config.txt with

```bash
sudo nano /boot/config.txt
```
and add the following lines at the end:

```plaintext
[pi1]
device_tree=bcm2708-rpi-b-plus.dtb
[pi2]
device_tree=bcm2709-rpi-2-b.dtb
[all]
dtparam=spi=on
dtparam=i2c1=on
dtparam=i2c_arm=on
dtoverlay=pitft28r,rotate=90,speed=32000000,fps=20
```

The `rotate=` variable tells the driver to rotate the screen **0 90 180 or 270** degrees.  
**0** is portrait, with the bottom near the USB jacks  
**90** is landscape, with the bottom of the screen near the headphone jack  
**180** is portrait, with the top near the USB jacks  
**270** is landscape, with the top of the screen near the headphone jack.  
You can change this file with **nano** and reboot to make the change stick.

The `speed=` variable tells the driver how fast to drive the display. 32MHz (**32000000**) is a good place to start but if your screen is acting funny, try taking it down to 16MHz (**16000000**) especially if
you’re doing something like using a GPIO extender to put the screen away from the Pi.

Save the file. Now we’ll just reboot to let it all sink in.

```
sudo shutdown -h now  # if you don’t have the TFT installed, shutdown, place the TFT on the Pi and re-power
```

or

```
sudo reboot  # if you have the TFT plate installed already
```

When the Pi restarts, the attached PiTFT should start out all white and then turn black. That means the kernel found the display and cleared the screen. If the screen did not turn black, that means that likely there’s something up with your connection or kernel install. Solder anything that needs resoldering!

Now that you’re rebooted, log back in on the console/TV/SSH. There’s nothing displayed on the screen yet, we’ll do a test to make sure everything is perfect first!

Run the following commands to startx on the /dev/fb1 framebuffer, a.k.a PiTFT screen:

```
sudo mv /usr/share/X11/xorg.conf.d/99-fbturbo.conf ~
export FRAMEBUFFER=/dev/fb1
startx
```
You should see the Pi desktop show up on the TFT! Congrats, you've completed the first test perfectly.

Hit Control-C in the console to quit the X server so we can continue configuration

Next up we'll add support for the touch screen automatically on boot. Edit the module list with

```
sudo nano /etc/modules
```

and add `stmpe-ts` on a line at the end
Save the file and reboot the Pi with `sudo reboot` and look at the console output (or run `dmesg` in the console window after logging in) you will see the modules install. Look in particular for the STMPE610 detection and the ILI9340 screen frequency as highlighted here.

![Console Output](image)

We can set up the touchscreen for `rotate=90` configuration by doing the following (for more delicate calibration or for other `rotate=XX` values, see the next section).

Create the directory and new calibration configuration file:

```
sudo mkdir /etc/X11/xorg.conf.d
```

```
sudo mkdir /etc/X11/xorg.conf.d
```
**sudo nano /etc/X11/xorg.conf.d/99-calibration.conf**

and enter in the following lines, then save.

```plaintext
Section "InputClass"
  Identifier  "calibration"
  MatchProduct  "stmpe-ts"
  Option  "Calibration"  "3800 200 200 3800"
  Option  "SwapAxes"  "1"
EndSection
```

You can now try to run X again with

```plaintext
FRAMEBUFFER=/dev/fb1 startx
```

Type Control-C to quit X

If you don't ever want to have to type FRAMEBUFFER=/dev/fb1 before startx, you can make it a default state by editing your profile file: **sudo nano ~/.profile** and adding

```plaintext
export FRAMEBUFFER=/dev/fb1
```
near the top and saving the file. Then reboot to reload the profile file. It will now always assume you want to use /dev/fb1
Touchscreen Install & Calibrate

If you've grabbed our Easy Install image, or use the script, this step is not required, it's already done! This is just for advanced users who are curious on how to configure and customize the touchscreen.

Setting up the Touchscreen

Now that the screen is working nicely, we'll take care of the touchscreen. There's just a bit of calibration to do, but it isn't hard at all.

Before we start, we'll make a udev rule for the touchscreen. That's because the eventX name of the device will change a lot and its annoying to figure out what its called depending on whether you have a keyboard or other mouse installed.

Run
sudo nano /etc/udev/rules.d/95-stmpe.rules

to create a new udev file and copy & paste the following line in:

```
SUBSYSTEM=="input", ATTRS(name)=="stmpe-ts", ENV[DEVNAME]=="*event*", SYMLINK+="input/touchscreen"
```

Remove and re-install the touchscreen with

```
sudo rmmod stmpe_ts; sudo modprobe stmpe_ts
```

Then type `ls -l /dev/input/touchscreen`
It should point to `eventX` where X is some number, that number will be different on different setups since other keyboards/mice/USB devices will take up an event slot
There are some tools we can use to calibrate & debug the touchscreen. Install the "event test" and "touchscreen library" packages with

```
sudo apt-get install evtest tslib libts-bin
```

Running `evtest`

Now you can use some tools such as `sudo evtest /dev/input/touchscreen` which will let you see touchscreen events in real time, press on the touchscreen to see the reports.
AutoMagic Calibration Script
If you rotate the display you need to recalibrate the touchscreen to work with the new screen orientation. You can manually run the calibration processes in the next section, or you can run a small Python script which will automatically set a default touchscreen calibration based on the screen orientation.

This helper is automatically installed for you but if you'd like you can check it out here on github (http://adafru.it/eIu)

Run it at the command line with `sudo adafruit-pitft-touch-cal`

it will try to figure out what display you have installed and the rotation it's set up for

By default the script will attempt to read the screen orientation by examining the PITFT module configuration with `modprobe`. If the script can read the orientation it will print out the current orientation, the current touchscreen calibration values, and the new touchscreen calibration values based on the current orientation. Before updating the calibration the script will ask you to confirm that you'd like to make the change. Press `y` and enter to confirm.
Try using this default calibration script to easily calibrate your touchscreen display. Note that the calibration values might not be exactly right for your display, but they should be close enough for most needs. If you need the most accurate touchscreen calibration, follow the steps in the next section to manually calibrate the touchscreen.

Manual Calibration

If the "automagic" calibration technique isn't working for you, or you have some other setup where you need to carefully calibrate you can do it 'manually'.

You will want to calibrate the screen once but shouldn't have to do it more than that. We'll begin by calibrating on the command line by running

```
sudo TSLIB_FBDEVICE=/dev/fb1 TSLIB_TSDEVICE=/dev/input/touchscreen
ts_calibrate
```

follow the directions on the screen, touching each point. Using a stylus is suggested so you get a precise touch. Don't use something metal, plastic only!
You should see five crosshair targets. If you see less than that, the touchscreen probably generated multiple signals for a single touch, and you should try calibrating again!

Next you can run `sudo TSLIB_FBDEVICE=/dev/fb1 TSLIB_TSDEVICE=/dev/input/touchscreen ts_test` which will let you draw-test the touch screen. Go back and re-calibrate if you feel the screen isn't precise enough!
X Calibration

You can also calibrate the X input system but you have to use a different program called `xinput_calibrator`

You can do this if the calibration on the screen isn't to your liking or any time you change the `rotate=XX` module settings for the screen. Since the screen and touch driver are completely separated, the touchscreen doesn't auto-rotate

Normally you'd have to compile it but we have a ready to go package for you so run:

```
sudo apt-get install -y xinput-calibrator
```
Before you start the xinput_calibrator you will need to delete the old calibration data so run

```
sudo rm /etc/X11/xorg.conf.d/99-calibration.conf
```

Before running `startx` and the calibrator - otherwise it gets really confused!

Now you’ll have to run the xcalibrator while also running X. You can do this by `startx` and then opening up the terminal program and running the `xinput_calibrator` command (which is challenging to do on such a small screen) OR you can do what we do which is run `startx` in an SSH/Terminal shell and then run the `xinput_calibrator` from the same shell, which requires the following command order:

```
FRAMEBUFFER=/dev/fb1 startx &
DISPLAY=:0.0 xinput_calibrator
```

Follow the directions on screen

```
Touchscreen Calibration
Press the point, use a stylus to increase precision.

(To abort, press any key or wait)
```

Once complete you’ll get something like:
Run `sudo nano /etc/X11/xorg.conf.d/99-calibration.conf` and copy the

```
Section "InputClass"
  Identifier    "calibration"
  MatchProduct  "stmpe-ts"
  Option "Calibration" "172 3763 3769 164"
  Option "SwapAxes" "1"
EndSection
```

or whatever you got, into there. You can quit X if you want by typing `fg` to bring that command into the foreground, and then Control-C to quit.

Depending on the 'rotation' of the screen, when you do this calibration, you may need to comment out the SwapAxes part with a `#` and/or swap the numbers around so looks like:

```
Option "Calibration" "119 3736 3850 174"
```

to

```
Option "Calibration" "3736 119 174 3850"
```

Your touchscreen is now super calibrated, hurrah!
Using the Console

One fun thing you can do with the display is have it as your main console instead of the HDMI/TV output. Even though it is small, with a good font you can get 20 x 40 of text. For more details, check out https://github.com/notro/fbft/wiki/Boot-console (http://adafru.it/cXQ)

First up, we'll update the boot configuration file to use the TFT framebuffer /dev/fb1 instead of the HDMI/TV framebuffer /dev/fb0

```
sudo nano /boot/cmdline.txt
```

you can also edit it by putting the SD card into a computer and opening the same file.
At the end of the line, find the text that says `rootwait` and right after that, enter in:
```
fbcon=map:10 fbcon=font:VGA8x8
```
then save the file.

On the next boot, it will bring up the console.

Note that the kernel has to load up the display driver module before it can display anything on it so you won't get the rainbow screen, a NooBs prompt, or a big chunk of the kernel details since the module is loaded fairly late in the boot process.

I think the VGA8x8 font is a bit chunky, you probably want 12x6 which is what is shown in the photo above. To change the font, run `sudo dpkg-reconfigure console-setup` and go thru to select Terminus 6x12
Package configuration

Please choose the character set that should be supported by the console.

If you don't use a framebuffer, the choices that start with "." will reduce the number of available colors on the console.

Character set to support:

- Latin - Vietnamese
- Thai
- Combined - Latin; Slavic Cyrillic; Hebrew; basic Arabic
- Combined - Latin; Slavic Cyrillic; Greek
- Combined - Latin; Slavic and non-Slavic Cyrillic

Guess optimal character set

<Ok>  <Cancel>

Package configuration

"VGA" has a traditional appearance and has medium coverage of international scripts. "Fixed" has a simplistic appearance and has a better coverage of international scripts. "Terminus" may help to reduce eye fatigue, though some symbols have a similar aspect which may be a problem for programmers.

If you prefer a bold version of the Terminus font, choose either TerminusBold (if you use a framebuffer) or TerminusBoldVGA (otherwise).

Font for the console:

- GohaClassic
- Terminus
- TerminusBold

<Ok>  <Cancel>
Turn off Console Blanking

You may notice the console goes black after 30 minutes, this is a sort of ‘power saving’ or ‘screensaver’ feature. You can disable this by editing /etc/kbd/config and setting the blank time to 0 (which turns it off)

```
BLANK_TIME=30
```
Starting dphys-swapfile swapfile setup.
want /var/swap=100MB, checking existing: keeping it done.

pi@raspberrypi ~ $ FRAMEBUFFER=/dev/fb1
startx -- -dpi 60_
How To Play Videos

You can play many types of videos on the screen, using mplayer you don't even need to run X and you can script the movies to play using Python. We'll show you how to just play one video for now. To demo, we'll use an mp4 of Big Buck Bunny for 320 pixel wide screens. Below we show you how to create/resize videos, but to make it easy, just download our version with:

```
wget http://adafruit-download.s3.amazonaws.com/bigbuckbunny320p.mp4
```

The video is 30MB which is a lot if you haven’t expanded your SD card yet. Before you do this, run sudo raspi-config to expand the SD card so you don’t run out of space!

If you don’t have mplayer yet, run
sudo apt-get update

sudo apt-get install mplayer

to install it. It may take a few minutes to complete

OK now you just have to run

mplayer -vo fbdev2:/dev/fb1 -x 240 -y 320 -framedrop bigbuckbunny320p.mp4

if your video is not sized for 320 wide, you may need to add a -zoom after -framedrop so that it will resize - note that this is quite taxing for the Pi, so it may result in a choppy or mis-synced video!
Converting/Resizing Videos

It's possible to play full length videos on the TFT plate, but since the screen is small and the Pi can't use hardware acceleration to play the videos it's best to scale them down to 320x240 pixels. This will be easier for the Pi to play and also save you tons of storage space. For this demo, we'll be using the famous Big Buck Bunny (http://adafruit.it/cXS) video, which is creative commons and also very funny!

You can download it from the link above, we'll be using the 720p AVI version.
To do the conversion itself, we suggest HandBrake (http://adafru.it/cXT) which works great and is open source so it runs on all operating systems! Download and install from the link. Then run the installed application and open up the AVI file from before. The app will pre-fill a bunch of information about it.

![HandBrake window](image-url)
Under **Destination** click **Browse**... to select a new MP4 file to save. Then under **Picture** change the **Width** to 320 (the height will be auto-calculated)

![HandBrake conversion settings](image)

Click **START** to begin the conversion, it will take a minute or two.
That's it! You now have a smaller file. Don't forget to play it on your computer to make sure it plays right before copying it to your Pi.
Displaying Images

You can display every day images such as GIFs, JPGs, BMPs, etc on the screen. To do this we’ll install `fbi` which is the frame buffer image viewer (not to be confused with the FBI agency!)

`sudo apt-get install fbi` will install it

Grab our lovely wallpaper with

```
wget http://adafruit-download.s3.amazonaws.com/adapiluv320x240.jpg
```

© Adafruit Industries

and view it with

```
sudo fbi -T 2 -d /dev/fb1 -noverbose -a adapiluv320x240.jpg
```

That's it!
Backlight Control
Controlling the backlight

There’s a 4-LED backlight on the TFT and it draws ~75mA at all times. There might be times you’d like to save some power and turn off the backlight. The screen and touchplate will still work, you just can’t see anything. We designed the board with the STMPE610 touchscreen controller which has 2 extra GPIO and tied one of them to the transistor that controls the backlight. You can use the command line to control the backlight.

Start by getting access to the GPIO by making a device link

```bash
sudo sh -c "echo 508 > /sys/class/gpio/export"
ls -l /sys/class/gpio
```

Please note, previous versions of the PiTFT kernel had the STMPE GPIO pin '252' not '508' so just substitute that number

Once you verify that you see GPIO #508, then you can set it to an output, this will turn off the display since it will output 0 by default

```bash
sudo sh -c "echo 'out' > /sys/class/gpio/gpio508/direction"
```

Then turn the display back on with

```bash
sudo sh -c "echo '1' > /sys/class/gpio/gpio508/value"
```
or back off

```
sudo sh -c "echo '0' > /sys/class/gpio/gpio508/value"
```
Extras!

Tactile switch as power button

It's a good idea to safely turn off your Pi with a good `sudo shutdown -h now` but that often means pulling out a keyboard or connecting to the console. With our kernel we added a cool module that will let you turn any GPIO into a power button. Since there's a couple of tactile switches right there on the front, let's turn one into a power button. Press once to properly turn off the Pi, press again to start it up. Isn't that nice?

We'll be using GPIO #23, the left-most button on a PiTFT 2.8", on the 2.4" HAT, #16 is a good choice since its on a tactile button. But, you can use any GPIO you want, really!

You will have to grab a pack of slim tactile switches ([http://adafruit.it/1489](http://adafruit.it/1489)) or otherwise solder in a button.

Add `rpi_power_switch` to `/etc/modules` and save.

Now create a new conf file or edit our existing one with

```
sudo nano /etc/modprobe.d/adafruit.conf
```

and enter in the line

```
options rpi_power_switch gpio_pin=23 mode=0
```

Of course, change the `gpio_pin` setting to some other # if you wish. `mode=0` means its a pushbutton not a switch. If you happen to install an on/off switch, use `mode=1`
To make it active immediately run `sudo modprobe rpi_power_switch`

Making it easier to click icons in X

If you want to double-click on icons to launch something in X you may find it annoying to get it to work right. In LXDE you can simply set it up so that you only need to single click instead of double. From LXDE launch the file manager (sorry these pix are grayscale, still figuring out how to screenshot the framebuffer!)

Then under the **Edit** menu, select **Preferences**
Then select **Open files with single click** and close the window (you'll need to drag it over to get to the X button)

---

**Boot to X Windows on PiTFT**

To enable booting straight to X windows on the PiTFT follow the steps below. First make sure a display configuration which would conflict is **not** present by executing in a terminal on the Pi:

```
sudo mv /usr/share/X11/xorg.conf.d/99-fbturbo.conf ~
```

Don’t worry if the command fails with an error that the file doesn’t exist. This failure is normal and should happen on a good PiTFT install. You can ignore it and move on.

Next run the command below to open the nano text editor as root and create the file `/usr/share/X11/xorg.conf.d/99-pitft.conf:`
When the editor loads to a blank file, copy in the text below:

```
Section "Device"
 Identifier "Adafruit PiTFT"
 Driver "fbdev"
 Option "fbdev" "/dev/fb1"
EndSection
```

Then save the file by pressing Ctrl-O and then enter, and finally exit by pressing Ctrl-X.

The step above will create a configuration file which tells X windows that it should use the PiTFT framebuffer (located at /dev/fb1) by default when it runs.

At this point you can use the raspi-config tool to enable booting to desktop just like normal on the Pi. Run the following command:

```
sudo raspi-config
```

Then pick the **Enable Boot to Desktop/Scratch** option and choose if you want to boot to the console, desktop, or scratch environment. After exiting the tool and rebooting you should see the Pi load X windows on the PiTFT after (be patient it can take around 30 seconds to load).

If you want to disable booting to X, just use the raspi-config command again to choose the console boot option.

### Right-click on a touchscreen

Obviously if you have a touchscreen, it cannot tell what finger you are pressing with. This means that all 'clicks' are left clicks. But if you want a right-click, you *can* do it.

Just add the following lines into your InputClass of `/etc/X11/xorg.conf.d/99-calibration.conf` after the calibration section

```
Option "EmulateThirdButton" "1"
Option "EmulateThirdButtonTimeout" "750"
Option "EmulateThirdButtonMoveThreshold" "30"
```

So for example your file will look like:
Section "InputClass"
  Identifier   "calibration"
  MatchProduct "stmpe-ts"
  Option "Calibration" "3800 120 200 3900"
  Option "SwapAxes" "1"
  Option "EmulateThirdButton" "1"
  Option "EmulateThirdButtonTimeout" "750"
  Option "EmulateThirdButtonMoveThreshold" "30"
EndSection

This makes a right mouse click emulated when holding down the stylus for 750 ms.

(Thx adamaddin! (http://adafruit.it/fH3))
Gesture Input

With the PiTFT touchscreen and xstroke (http://adafruit.it/dD0) you can enter text in applications by drawing simple character gestures on the screen! Check out the video below for a short demonstration and overview of gesture input with xstroke:

Installation

Unfortunately xstroke hasn’t been actively maintained for a few years so there isn’t a binary package you can directly install. However compiling the tool is straightforward and easy with the steps below. Credit for these installation steps goes to mwilliams03 at ozzmaker.com (http://adafruit.it/dD1).

First install a few dependencies by opening a command window on the Pi and executing:

```bash
sudo apt-get -y install build-essential libxft-dev libxpm-dev libxtst-dev
```

Now download, compile, and install xstroke by executing:

```bash
cd ~
wget http://mirror.egtvedt.no/avr32linux.org/twiki/pub/Main/XStroke/xstroke-0.6.tar.gz
tar xfv xstroke-0.6.tar.gz
cd xstroke-0.6
./configure
sed -i'^X_LIBS = / s/$/ -lXrender -lX11 -lXext -ldl/" Makefile
make
sudo make install
```

If the commands above execute successfully xstroke should be installed. If you see an error message, carefully check the dependencies above were installed and try again.

Once xstroke is installed you will want to add a couple menu shortcuts to start and stop xstroke. Execute the following commands to install these shortcuts:

```bash
wget https://github.com/adafruit/PiTFT_Extras/raw/master/xstroke.desktop
wget https://github.com/adafruit/PiTFT_Extras/raw/master/xstrokekill.desktop
sudo cp xstroke*.desktop /usr/share/applications/
```

Usage

To use xstroke I highly recommend using a plastic stylus instead of your finger. Also calibrate the touchscreen for X-Windows (http://adafruit.it/dD2) so you have the best control over the cursor.
Start X-Windows on the PiTFT and open the LXDE menu by clicking the icon in the lower left corner. Scroll up to the Accessories menu at the top and notice the new XStroke and XStroke Kill commands.

Click the XStroke menu option to start xstroke. You should see a small pencil icon appear on the bottom right side of the screen. The pencil icon means xstroke is running, however by default it's not yet looking for gesture input.

Open an application that takes text input, such as LXTerminal. To enable gesture input click the xstroke pencil icon. You should see the pencil turn green and the text 'abc' written over top of the icon. You might need to click the icon a few times to get the click to register in the right spot.

When xstroke is looking for gesture input you can drag the mouse cursor in a gesture anywhere on the screen to send specific key strokes. Here's a picture of the possible gestures you can send:

Don't use a ballpoint pen or sharp metal stylus as it could scratch or damage the touchscreen!
To draw a gesture from the above image, press anywhere on the screen, start from the circle in the gesture, and follow the gesture pattern towards the arrow. As you draw a gesture you should see a blue line displayed that shows what you’ve drawn. Lift up the stylus when you get to the end of the gesture at the arrow. If xstroke recognizes the gesture it will send the appropriate key press to the active window. Try drawing a few characters from the image above to get the hang of writing gestures.

A few very useful gestures are backspace (which deletes a character), return/enter, and space. To draw a backspace gesture just draw a line going from the right side of the screen to the left side. The gesture for return/enter is a diagonal line from the top right to bottom left. Finally a space is a straight line from the left to the right.

Note that when xstroke is looking for gestures you might not be able to click or control the cursor as you normally would expect. To stop xstroke’s gesture recognition carefully press the xstroke pencil icon again until the ‘abc’ text disappears. I’ve found this process can be a little finicky as the icon is

(credit to Carl Worth for the image above)
very small and any movement will be interpreted as a gesture. Use a light touch and try a few times to click the icon.

If you get stuck completely and can't disable xstroke by clicking the icon, connect to the Raspberry Pi in a terminal/SSH connection and run 'killall xstroke' (without quotes) to force xstroke to quit. The normal way to stop xstroke is to navigate to the Accessories -> XStroke Kill command, but you might not be able to do that if xstroke is listening for gesture input.

Have fun using xstroke to control your Pi by writing gestures on the PiTFT screen!
FAQ

My PiTFT used to work, now it doesn't!
Did you do an `apt-get upgrade` or `rpi-update`? This command will blow away our PiTFT kernel which means that you will no longer have PiTFT support, you will have to redo the `easy-install` steps to reinstall the kernel.

If you had already made a working PiTFT setup, you may be able to reinstall the Adafruit kernel like so:

```bash
sudo apt-get install raspberrypi-bootloader=1.20150528-1
```

If it tells you that the latest version is already installed, try this instead:

```bash
sudo apt-get install --reinstall raspberrypi-bootloader=1.20150528-1
```

...you can check here [http://adafru.it/eUK](http://adafru.it/eUK) and substitute the most recent version you see in the `=1.20150528-1` part.

My PiTFT works for a bit and then I get a black screen with a short line of white pixels in one corner

Sounds like you tried to configure your Pi to 'boot straight to X', that is, start up the graphics interface on boot. This doesn't work by default because the Pi operating system is not expecting a PiTFT so it boots to the HDMI output. See below for how to set up your Pi to boot to X on the PiTFT

To 'fix' this, you can either connect an HDMI monitor, then in a terminal window run `sudo raspi-config` and configure the Pi to boot to the command line not X! If you do not have an HDMI monitor, you can also try a console cable

How can I force the Pi to bring up X on the HDMI/TV monitor?

Use the `fb0` framebuffer when you want to display stuff on the HDMI/TV display, for example:

```bash
FRAMEBUFFER=/dev/fb0 startx
```

will use the HDMI/TV framebuffer for X windows instead of the PiTFT

That doesn't work! I can't get X on HDMI!

If both

```bash
FRAMEBUFFER=/dev/fb0 startx &
```

and

```bash
FRAMEBUFFER=/dev/fb1 startx &
```

wind up showing the GUI on your PiTFT, enter the following instruction from the command line:

```bash
sudo mv /usr/share/X11/xorg.conf.d/99-fbturbo.conf ~
```
I'm trying to run startx and I get FATAL: Module g2d_23 not found.  
Don't forget you have to remove the turbo file!

```
sudo mv /usr/share/X11/xorg.conf.d/99-ftb turbo.conf ~
```

Why doesn't the tactile button on GPIO #21 work?
On some older PiTFTs we had one of the buttons labeled #21 - that's the original RasPi name for that pin. If you're using a V2 (chance is, you are!) that is now called #27.
All the PiTFT's we ship now have the button labeled #21 and #27

I want better performance and faster updates!
You can change the SPI frequency (overclock the display) by editing `/boot/config.txt` and changing the `dtoverlay` options line to:

```
dtoverlay=pitft28r,rotate=90,speed=62000000,fps=25
```

Or whatever you like for speed, rotation, and frames-per-second. BUT, here's the thing, the Pi only supports a fixed number of SPI frequencies. So tweaking the number a little won't do anything. The kernel will round the number to the closest value. You will always get frequencies that are 250MHz divided by an even number. Here's the only SPI frequencies this kernel supports:

- 15,625,000 (a.k.a 16000000 = 16 MHz)
- 17,857,142 (a.k.a. 18000000 = 18 MHz)
- 20,833,333 (a.k.a 21000000 = 21 MHz)
- 25,000,000 (= 25 MHz)
- 31,250,000 (a.k.a 32000000 = 32MHz)
- 41,666,666 (a.k.a 42000000 = 42MHz)
- 62,500,000 (a.k.a 62000000 = 62MHz)

So if you put in 48000000 for the speed, you won't actually get 48MHz, you'll actually only get about 42MHz because it gets rounded down. We tested this display nicely with 32MHz and we suggest that. But you can put in 42MHz or even try 62MHz and it will update faster.

You can tweak fps (frames per second) from 20 to 60 and frequency up to 62MHz for tradeoffs in performance and speed. Reboot after each edit to make sure the settings are loaded properly. There's a trade off that if you ask for higher FPS you're going to load the kernel more because it's trying to keep the display updated.

How can I take screenshots of the little screen?

We took the screenshots for this tutorial with

We took the screenshots for this tutorial with

```
wget http://fbgrab.monells.se/fbgrab-1.2.tar.gz
```

tar -zxvf fbgrab*gz

cd fbgrab/

make

./fbgrab screenshot.png

How do I automatically boot to X windows on the PiTFT?

Once you have a PiTFT installation setup you can add a custom X windows configuration to use the PiTFT by default. Then you can use the normal raspi-config boot to console/desktop options to control if the Pi boots to a console or desktop. See the detailed instructions on this page of the guide (http://adafruit.it/e1s) for more information.

My screen isn’t working/works erratically/looks funny

Check to make sure that the flat flex cable is fully seated in the connector and the ‘ears’ are pushed in to secure it. See the picture for what it should look like:
On my first run of startx I get a window saying "GDBus Error.org.Freedesktop Policy Kit1 Error: Failed Cannot determine user of subject"

This happens on the Raspberry Pi the first time you run startx, no matter what display. You can just re-start X and it wont appear again.

Can I get a right-click from the touch-screen?
Yes! Please see this post:
